Received 13 June 2005; revised 23 September 2005; accepted 11 October 2005; published 6 December 2005.

The eigenvalue analysis for the upper-hybrid/Langmuir waves trapped in cylindrical density structures is carried out. Under physical parameters typical for kilometric continuum (KC) source region, it is found that the frequency spacing between individual fine structure spectrum is within a reasonable observed range of 0.1–1 kHz. It is also found that the quasi field-aligned modes are associated with density cavities, while the radial modes are excited within enhanced density column, thus showing that density irregularities of various types can support discrete wave spectrum featuring wide-ranging frequency gaps. 1. Introduction

[2] Hashimoto et al. [1999] described kilometric continuum (KC) as emission that lies in the same frequency range as auroral kilometric radiation (AKR) [cf. Gurnett, 1974], but with a different spectral morphology and a unique source region, the low-latitude, inner plasmasphere. KC was observed by Geotail (in an equatorial orbit) to consist of slowly drifting narrowband signals in the frequency range 100 kHz < f < 800 kHz. Direction-finding using spin modulation of the emission at 400 kHz indicated that the source is consistent with the low-magnetic-latitude inner plasmasphere. The emission thus has much in common with non-terrestrial continuum emission [cf. Gurnett and Shaw, 1973; Gurnett, 1975] observed at lower frequencies (typically < 100 kHz).

[3] Menietti et al. [2003] reported high resolution observations made by the plasma wave instrument (PWI) on board the Polar spacecraft as it was passing through the source region of the KC emission observed also by Geotail. These wideband measurements indicated not just emission at fce and its (n + 1/2) harmonics, but at multiple wave frequencies separated in frequency by f ≪ fce. The authors conclude that these fine-structure emissions were consistent with electrostatic (ES) upper-hybrid (UH) emissions as well as electromagnetic (EM) Z and O-mode waves. In addition, Menietti et al. [2005] discussed Polar and Cluster observations of continuum emission fine structure. High resolution waveform data from Polar were used to directly measure the polarization of continuum emission and the direction of propagation. The authors found that the continuum emission at high resolution has a fine structure very similar to KC emission. One explanation for such emission is that it is due to multiple sources located at different radial distances (hence frequency). A radial separation of <1000 km could explain differences of fce of only a few hundred Hz. It is also known that density fluctuations in the form of cavities and ducts are present in the plasmasphere [e.g., LeDuc et al., 1994; Darrouzet et al., 2002, 2004; Carpenter et al., 2002].

[4] Decreau et al. [2004] observed many examples of continuum emission, some associated with electron cyclotron harmonics within the plasmasphere and near the plasmapause. The Cluster satellites encounter continuum emission source regions, which appear to be located near the magnetic equator as well as well away from the equator. Decreau et al. [2004] show evidence that the source regions are likely associated with density cavities. Darrouzet et al. [2004] conducted a statistical study of the Cluster WHISPER and EFW (electric field and waves) data to obtain a sample of the nature and extent of density irregularities observed within the plasmasphere. These authors found that the characteristic transverse equatorial size is about 365 km. The characteristic density depletion ratio is 20%.

[5] The IMAGE satellite has made recent advances in the study of small-scale field aligned density structures of the plasmasphere. Carpenter et al. [2002] report the results of a study of data from the Radio Plasma Imager (RPI) onboard the satellite. This instrument uses active sounding techniques from a range of frequencies. These authors conclude, based on earlier evidence from topside sounders and whistler mode instruments [Muldrew, 1969] that density irregularities have cross-field scale sizes within the range of ~200 m to over 10 km and electron densities within ~10% of background values. Jacobson and Erickson [1993] used a Very Large Array radio interferometer to detect density irregularities extending 30 to 40 km transverse to the magnetic field with density fluctuations less than 10% of background. These irregularities were observed within the plasmasphere for L < 2. Calvert and Warnock [1969] used topside sounder data and “combination mode ducting” as evidence for density irregularities elongated in the direction of the geomagnetic field. Fung et al. [2003] have reported RPI observations of IMAGE for the outer plasmasphere (300–600 kHz) and plasmapause (100–200 kHz) that support a range of cross-field scales for density irregularities in the range ~0.25–2 km, consistent with the work of

Figure 1. Upper-hybrid/Langmuir dispersion relation \( \omega/k \) surface versus \( k_{\perp} \nu /\sqrt{2} \Omega \) and \( k_{\parallel} \nu /\sqrt{2} \Omega \).

Carpenter et al. [2002]. Eigenmode trapping of Z-mode emissions for both density cavities and density enhancements [cf. McAdams et al., 2000; Yoon et al., 2000] has been suggested to explain discrete emissions (fine structure) of auroral roar. A modification of such processes might also explain the plasmaspheric observations of continuum and kilometric continuum.

2. Trapped Eigenmode Theory in Density Irregularities

[6] We assume that uniform magnetic field is along the z axis while the density gradient is in the radial direction. Quasi ES waves trapped in the density structure are assumed to have wave frequency near the local upper-hybrid frequency, \( \omega \approx \nu_{\text{uh}} = (\nu_r^2 + \nu_0^2)^{1/2} \), or plasma frequency \( \omega \approx \nu_{\text{m}} \), where \( \nu_r^2 = 4\pi n(r) e^2/m \) and \( \Omega = eB/\text{mc} \). Conversion to O mode radiation is necessary for these waves to be detected from a distance.

[7] The nonlocal wave equation can be obtained from Vlasov-Maxwell linear theory. It is possible to derive the following coupled wave equation — derivation is omitted for lack of space, but full discussion will follow in a regular-length article:

\[
0 = \frac{1}{r} \frac{d}{dr} \left( r \frac{d \phi}{dr} \right) - \frac{m^2}{c^2r^2} \phi - k_{\parallel}^2 \frac{\omega^2 - \omega_p^2}{\omega^2 - \omega_r^2} \phi,
\]

where \( \phi \) is the wave electric potential associated with the trapped ES mode, and \( A \) is the z-component of the vector potential which represents the O-mode radiation. (1) shows that once ES eigenfunction \( \phi \) is obtained, the EM mode \( A \) is automatically generated. Note that O-mode couples to ES mode when \( k_{\parallel} \) is finite. Mode-converted O-mode is expected to be generated in an oblique direction with respect to the density gradient. In what follows, we focus on the ES wave equation only. Full analysis of the entire coupled mode equation (1) is the subject of a future full-length paper.

[8] In the local approximation \( (\nabla, \rightarrow ik_{\parallel}) \), the first equation in (1) is an algebraic equation. Figure 1 shows the local dispersion relation for \( \nu_r/\Omega = 1.5 \). Note that for quasi-perpendicular propagation the waves can be characterized as the upper-hybrid waves, while for quasi-parallel propagation the waves behave in a Langmuir wave-like manner. In what follows, we shall thus consider the above two extreme cases.

[9] For quasi-parallel propagation, where we may ignore the highest-order derivative and assume that \( \phi(r) = \phi(r) \exp(\text{im}_0 \phi), m = 0, 1, 2, \ldots \), where \( \phi \) represents the azimuthal angle. Then we have

\[
\frac{d}{dr} \left( r \frac{d \phi}{dr} \right) - \frac{m^2}{c^2r^2} \phi - k_{\parallel}^2 \frac{\omega^2 - \omega_p^2}{\omega^2 - \omega_r^2} \phi = 0.
\]

Let us denote the density at the axis of the cylindrical density structure by \( n(0) \). In the vicinity of the axis, we may approximate \( n(r) \approx n(0) + n'(0) r^2/2 \). This leads to

\[
0 = \frac{1}{r} \frac{d}{dr} \left( r \frac{d \phi}{dr} \right) + k_{\parallel}^2 \left( \frac{1 - \nu_r^2}{\nu_r^2} \right) \phi - \frac{m^2}{c^2} \phi,
\]

\[
k_{\parallel} = \frac{\omega_p^2 - \Omega^2}{\omega^2 - \omega_p^2},
\]

\[
r_{0}^2 = \frac{2n(0) - \omega_p^2}{n'(0) - \omega_p^2}.
\]

[10] To obtain the discrete spectrum, we employ the eikonal matching condition [McAdams et al., 2000; Yoon et al., 2000],

\[
\left( j + \frac{1}{2} \right) \pi = k_0 \int_{r_0}^{r_{00}} dr \left( 1 - \frac{r^2}{r_0^2} - \frac{m^2}{k_0^2 r^2} \right)^{1/2},
\]

where \( r_{00}/r_0 = [1 \pm (1 - 4n^2/k_0^2 r_0^2)^{1/2}] /2 \), and \( j = 0, 1, 2, \ldots \). Carrying out the integration, we obtain

\[
k_0 r_0 = 8(j + m/4 + 1/2),
\]

from which we obtain an approximate expression for the discrete eigenfrequency,

\[
\omega_{j,m} \approx \omega_p(0) + (j + m/4 + 1/2) \Delta \omega,
\]

\[
\Delta \omega = \frac{\omega_p(0) \sqrt{\nu_r^2 - \nu_0^2}}{k_{\parallel} \sqrt{n'(0)/n(0)}},
\]

The quantity of interest is the frequency spacing between individual fine structure spectrum, \( \Delta \omega \). For \( \omega_p(0) < \nu_r^2 \), which is valid for the plasmasphere, only the density depletion \( n'(0)/n(0) > 0 \) will support the discrete wave spectrum. In the opposite case, namely, \( \omega_p(0) < \nu_r^2 \), it will be the enhanced density column \( n(0)/n(0) < 0 \) which supports discrete trapped eigenmodes instead.

[11] Let us assume that plasmaspheric electron temperature is \( T_e \sim 1 \text{ eV} \), the number density is roughly \( n_e \sim 50 \) per c.c., and that the ratio of electron plasma frequency to gyrofrequency is on the order of \( \sim 10 \) or so. If we assume that the free energy source of the discrete waves is a field-
aligned energetic electron beam with typical average beam speed roughly ten times the thermal speed $V_0/v_T \sim 10$, and that the characteristic wave number associated with the waves excited by such a beam satisfies the Landau resonance condition $k_l V_0/\omega_p(0) \approx 1$, then we find that the order of magnitude estimate of the frequency spacing is $\Delta \omega/\omega_p(0) \approx 10^{-5} v_T(\omega_p L) \approx 10^{-3} L^{-1}$, where $L$ is the characteristic width associated with the density cavity measured in km’s. If we assume that the plasma frequency $f_p(0) = \omega_p(0)/(2\pi)$ is on the order of 100 kHz or so, then for 1 km density structure width, we have the frequency width $\Delta f = \Delta \omega/(2\pi) \sim 0.1$ kHz. Clearly, wider density structure will lead to even narrower frequency spacing and vice versa.

In the case of quasi-perpendicular wave propagation, we may ignore $k_l$ in the first equation of (1):

$$0 = \frac{1}{r} \frac{d}{dr} r \frac{d}{dr} - \frac{m^2}{r^2} \phi - \frac{2\Omega^2 (\omega^2 - \omega_p^2)}{v_T \omega_p^2} \phi. \tag{5}$$

Upon expanding the density in Taylor series about the cylinder axis as before, (5) can be shown to reduce to the same form as (3), except that the quantities $k_0$ and $r_0$ are now defined by

$$k_0^2 = \frac{2\Omega^2 [\omega_p^2(0) + \Omega^2 - \omega^2]}{v_T \omega_p^2 \omega^2},$$

$$r_0^2 = \frac{2m(0) \omega_p^2(0) + \Omega^2 - \omega^2}{-n_r(0) \omega_p^2(0)}. \tag{6}$$

The resulting discrete upper-hybrid wave dispersion relation is approximately given by

$$\omega_{uh,m} \approx \omega_{uh}(0) - (j + m/4 + 1/2) \Delta \omega,$$

$$\Delta \omega = 2v_T \sqrt{\frac{\omega_p^2(0)}{\Omega^2} \sqrt{\frac{\omega_p^2(0)}{n_r(0) n_0}}} \Delta \omega. \tag{7}$$

According to (7), for the upper-hybrid waves to be trapped in cylindrical density structure, it must feature an enhanced density along the density tube. A rough estimate of $\Delta \omega$ making use of the same physical parameters as before shows that in the case of enhanced density column $\Delta \omega/\omega_p(0) \approx 10^{-1} L^{-1}$. This shows that for 100 kHz upper-hybrid mode frequency, the density structure of 10 km radius will give $\sim 1$ kHz frequency spacing.

3. Conclusions

To conclude, in this article we have carried out the eigenvalue analysis for the upper-hybrid/Langmuir waves trapped in cylindrical density structures. The method of the analysis is similar to that considered by McAdams et al. [2000], who emphasized the quasi-parallel trapped Langmuir waves, and by Yoon et al. [2000], who paid special attention to upper-hybrid waves trapped in density enhancement. In the present analysis, we have provided a unified formalism which encompasses both situations.
